Overview

In database management, archival and purging are distinct processes for managing data lifecycle. **Archival** is preserving, organizing, and storing records, documents, or data for long-term retention. This process will clear and store data from original tables in backdated archive tables. **Purging**, on the other hand, is the permanent deletion of data that is no longer needed. Often, archiving precedes purging, allowing for data preservation before its final removal.

The **archiving process** is configured as a job that runs at a scheduled interval and archives past data based on the number of days specified.

Two procedures are created as part of the archival process:

1. **archive_and_delete_proc** : Archives data from customer-related tables.
2. **archive_logs_and_delete_proc** : Archives data from log-related tables.

Prerequisites

All archival-related tables and procs will be created automatically as part of the Spotlight installation. An **ArchivalJob** with default configurations will be created as part of the installer. The job points to ArchivalJavaService > performArchiveOperation, which will internally call the procs (**archive_and_delete_proc**, **archive_logs_and_delete_proc**) via Java code.

Job Configuration

All the configurations related to the Archival job can be configured by following the below mentioned steps:

1. Login to Fabric.
2. Click on Environments > App Services.

3. In the App Services tab, click on **Jobs**.
4. Click on the three dot menu against the archival job and choose the **Edit** option.
5. Under the Job Info screen, only the UserName, Password, History Strategy, History Retention Period, Description, and Email Notification on Failure fields can be changed as needed.
6. Under the **Schedule tab**, the frequency and timings of the job can also be changed.
7. Click on **Update** after changing configurations.
8. Job Run history can be viewed under View Job History.

Settings Configuration

For Settings Configuration follow the below mentioned steps:

1. Login to Fabric.
2. Click on Environments > App Services.
3. In the App Services tab, click on the Settings tab.
4. In Server Properties, search for **ARCHIVE_NUM_OF_DAYS** and update the value based on need; the default value is 90.

Archival Tables

The listed tables store critical logs, notifications, requests, and approval records that accumulate large volumes of data over time. The dbxlogs schema primarily contains logs related to admin activity, audits, and financial transactions, such as moneymovementlog, which tracks money transfers. The dbxdb schema holds operational and customer-related data, including notification for system alerts, customerrequest for user-initiated actions, and alerthistory for historical alerts. Additionally, several tables like approvalmatrix and signatorygrouprequestmatrix,

manage approval workflows and authorization structures, making them essential for compliance and governance. Given their size and relevance, regular data archival or purging should follow a bank-defined schedule to ensure system efficiency.

Below are the tables that hold large amounts of data and need data archival or purging at a standard frequency, which the bank can define:

Table	Description
dbxlogs.adminactivity	This table will be populated during admin activity in the spotlight application. For instance: 1. When the admin is performing a customer search in the customer management module, details of his search activity are logged in this table. 2. Maker-Checker flows like admin approved or rejected are also logged in this table.
dbxlogs.auditactivity	This table will be populated with customer activity in OLB and MB applications. For instance: • Customer logged in • Accounts fetch
dbxlogs.moneymovementlog	This table will be populated with payment data (from account number, amount, to account number, etc.) when payments are made from OLB and MB applications.

Scripts

Find the path for the files, to view the scripts for archival. These scripts will already be a part of the database when dbxdb migration is performed.

•archive_and_delete_proc

Spotlight_App-v202504.xxx

•archive_logs_and_delete_proc

Spotlight_App-v202504.xxxx

Output

After running the job, the entries are moved to the Archival table, generating the following outputs.

1. Before triggering the job
2. After triggering the job
