Overview

Data Scrambling is a technique used to obfuscate or modify data to make it unreadable or unusable while preserving its structure. It is commonly used in software testing, database security, and compliance to protect sensitive information.

The scrambling utility will scramble the complete PII data in the DBXDB to a default value mentioned in the **config.properties** file.

Prerequisites

Note: Do not execute the jar in the production environment; this applies only to lower environments.

1. Download the **scrambling utility zip** from the distribution folder.
2. Change values in the **db.properties** file present inside the **Scrambling_Tool_Source_Code** folder.

The values in the **db.properties** must be updated with the correct DB details of the environment where the utility tool must be executed.

3. Change values in the **config.properties** file (if required).

The **config.properties** file can be edited as necessary.

How to Run the Utility

- **Step 1:** Extract the contents from the **zip** provided by the distribution team.
- **Step 2:** Edit the **db.properties** file, placing the correct DB details, which are present inside the **Scrambling_Tool_Source_Code** folder.
- **Step 3:** Edit the **config.properties** file inside the **scramblingutility.jar** if any custom tables are to be added or existing table values are to be edited.

- **Step 4:** Navigate inside the binaries folder, where the **scramblingutility.jar** is present.
- **Step 5:** Open the **cmd prompt** from the folder where the utility jar is present..
- **Step 6:** Execute **java -Ddb.config="C:\Users\xxxxxx\Downloads\DataScrambling_ToolKit-v25.0.0\Scrambling_Tool_Source_Code\db.properties" -jar scramblingutility.jar**.
- **Step 7:** Once the command is executed, a log file will be created where any errors can be verified if they are logged.

Output

Screenshot before Running the Jar

In the below screenshot, the account name displayed in the dashboard is the nickname of the accounts before executing the utility jar.

Note: Screenshot is not added due to copyright issue

Screenshot after Running the Jar

The **config.properties** file in the jar has the default values to scramble in the database. The account names are scrambled to the default values that were specified in the **config.properties** file.
